Abstract. In order to reduce load impact and hydraulic leakage happened in the process of locked rope switching or stroke arrival for the present rope changing devices, a novel type of rope changing device with clamping chain transmission is designed based on the "pipe forming mechanism". The new device fundamentally improves the safety and stability of steel-rope. By theoretical deduction, the steel-rope transverse vibrations in rope changing of the new device are calculated. Results show that the compacting force of locked-rope mechanism can reduce the transverse vibration amplitude by 80 % or more, which is caused by the polygon effect in chain transmission; as the increasing rigidity of locking disc spring, the limitation for transverse vibration displacement of wire rope becomes stronger, and the effect is fading when the rigidity reaches a certain value. Transverse vibration trends of steel-rope from test are consistent with the theoretical calculation results, which verify the correctness of the theoretical calculation; The maximum vibration amplitude of steel-rope is less than 0.4mm, effectively limiting the transverse vibration caused by the polygon effect in chain transmission and making the steel-rope work continuously and smoothly.

Keywords: clamping chain transmission, rope changing device, transverse vibration, modeling and simulation.

1. Introduction

Increasing exhaustion of shallow resources brings great growth of large-scale 1000-plus deep mines. Lifting steel-rope with larger diameter and self-weight, together with more complicated load impacts in internal torsion, bending and stretching applied in deep mines draws higher requirements for security in rope changing [1-3]. Commonly-used auxiliary tool-chain block can't apply to such heavy-load conditions [4-8]. A series of studies on rope changer have solved the problems of lager-diameter rope changing in heavy-load conditions, however hydraulic leakage, seal-aging and joint line breakage still lead to security risks due to the long duration working mode of its hydraulic power mechanism. Furthermore, the transverse vibration caused by stroke arrival of hydraulic cylinder and repeated rope switching results in serious problems, i.e. "rope slipping", "rope twisting" or "rope skipping" in lifting steel-rope changing, which sometimes bring about catastrophe failure [9-12]. In order to find a solution for the existing problem in rope changer, this study has found a kind of rope changer with double-chain transmission based on the "pipe forming mechanism".

Since steel-rope vibration may cause load fluctuation, bounce, impact and bring about accidents, these studies on steel-rope vibration have attracted many scholars and they have made quite gratifying achievements in both theoretical derivation and experimental tests. Shi-Rong Yan [13] has conducted modeling calculation for the deformation of steel-rope in downward movement and analyzed the influence of variable stiffness and mass on steel-rope vibration. Guo-Hua Cao [14] has conducted modeling calculation considering the impact of variable stiffness effect on

steel-rope in the loading process and analyzed vibration characteristics of skip loading and cage. Yu-Qiang Jiang [15] has established the coupling dynamics model for hoisting system of the flexible space 6 degree of freedom and studied the nonlinear coupling characteristics of cage. On the basis of previous studies, calculation of steel-rope transverse vibration in rope changing of rope changer with clamping chain transmission and experimental tests have been conducted in this paper.

2. Rope changer with clamping chain transmission

As is shown in Fig. 1, rope changer with clamping chain transmission comprises two groups of transmission chains, two groups of driving chain wheels, two groups of driven chain wheels, disc spring hydraulic cylinder, screw jack, force transmission frame, chain tension mechanism, fixing racks, rope guide module and connectors. Two groups of transmission chains and wheels can achieve rope receiving and releasing; disc spring hydraulic cylinder, screw jack and force transmission frame constitute the locking module, applying the working mode of "loosening rope by hydraulic pressure and locking rope by resetting the disc spring"; chain tension mechanism provides stable tension for chains by "threaded adjusting and locking".

Rope changer with clamping chain transmission device achieves rope receiving and releasing based on "pipe forming mechanism". As is seen in Fig. 1, driving chain wheels put two groups of chains in circulatory motion under the drive of "frequency conversion brake motor decelerator"; the horizontal chain in the middle drives the lifting steel-rope to make linear motion forward or backward, transforming circular motion of chain wheels into continuous linear motion of lifting rope, and motions of rope receiving and releasing keep going without interruption. Screw jack and disc spring hydraulic cylinder make groove with wheels in chains press lifting steel-rope tight and provide stable and reliable rope locking power by thrust frame. Chain tension is adjusted by pulling the connecting shaft of driven chain wheel with tension mechanism.

Fig. 1. Structural diagram of rope changer with chain transmission

The device achieves continuous non-stop change of lifting steel-rope, avoiding stroke arrival of rope releasing mechanism and impact of load vibration caused by repeated switching between rope locking and loosening, and improves the efficiency of rope changing. Start and stop of the device are controlled by frequency conversion and rope changer runs more smoothly. Though the rope changer has fundamentally improved security and stability of rope changing devices, chain transmission with polygon effect still brings transverse vibration. Thus, the study on transverse vibration characteristics of the new device will help to understand vibration rule and optimize its functions.

3. Vibration model

3.1. Model analysis

In order to make deep analysis of its vibration characteristics, the device is simplified as theoretical model. Since clamping force of twin rope is achieved by reset force of disc string, the contact point of thrust frame and groove roller in the chain can be simplified as an elastic support; lifting steel-rope is located in the middle of two symmetrical chains and a group of chains is chosen as object of study to show vibration of lifting steel-rope in receiving and releasing [16-20]. Simplified model is shown in Fig. 2.

$$Y = \begin{pmatrix} & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & & \\ & & & & \\ & & & & \\ & & & & & \\ & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & &$$

Fig. 2. Dynamics model of transverse vibration with clamping chain transmission

For the convenience of theoretical analysis to grasp vibration rules of steel-rope in rope changing, here several hypotheses are made: (1) tension between chain links is equal; (2) vibration appears only in the plane of the chain wheel; (3) with its mass ignored, steel-rope vibrates together with the vibration of the compacted chain in the whole process; (4) mass, pitch and moment of inertia for each chain link are equal; (5) disc spring hydraulic cylinder is simplified as an elastic supporting module.

1) System kinetic energy analysis

Assumed that the center of gravity of chain link i is its geometric center, then the chain link i lateral displacement y_i^* deviate from the equilibrium position can be expressed as:

$$y_i^* = \frac{y_i + y_{i-1}}{2},\tag{1}$$

where y_i and y_{i-1} are lateral displacement of hinge centers at both ends of chain link *i*.

Because that the chain contact with the wire rope around its geometric center angle is very small, the rotation angle of chain i can be represented by the lateral displacement of both ends of the hinge:

$$\theta_i^* = \frac{y_i - y_{i-1}}{h},\tag{2}$$

where *h* is hinge pitch; θ_i^* is the rotation angle of chain *i*.

By the Eq. (1) and (2), the chain link i speed of its center of gravity in the y direction can be obtained as:

$$\dot{y}_i^* = \frac{\dot{y}_i + \dot{y}_{i-1}}{2} + \frac{y_i - y_{i-1}}{h}\nu, \tag{3}$$

where v is longitudinal velocity; The second term of the above formula is the transverse velocity component of the chain caused by the longitudinal velocity V of the chain.

According to Eq. (2), the rotation speed of chain link i around its geometric center can be

obtained as:

$$\dot{\theta}_{i}^{*} = \frac{\dot{y}_{i} - \dot{y}_{i-1}}{h}.$$
(4)

The chain link is approximately regarded as the rod around its rotation center in the calculation of inertia moment of link, the moment of inertia can be expressed as:

$$I_i = \frac{m_i h^2}{12},\tag{5}$$

where m_i is mass of chain link *i*; I_i is moment of inertia of chain link *i*.

According to mechanical analysis of the model, and by combining Eq. (3), (4) and (5), kinetic energy of the system can be obtained as:

$$T = \frac{1}{2} \sum_{i=1}^{N} m_i (\dot{y}_i^*)^2 + \frac{1}{2} \sum_{i=r+1}^{N} I_i (\dot{\theta}_i^*)^2 + \frac{1}{2} m_b \dot{y}_b^2$$

$$= \frac{1}{2} \sum_{i=1}^{N} m_i \left(\frac{\dot{y}_i + \dot{y}_{i-1}}{2} + \frac{y_i - y_{i-1}}{h} v \right)^2 + \frac{1}{24} \sum_{i=r+1}^{N} m_i (\dot{y}_i - \dot{y}_{i-1})^2 + \frac{1}{2} m_b \dot{y}_b^2,$$
(6)

where m_b is mass of force transmission frame; and y_b is transverse vibration displacement of guide rail.

2) System potential energy analysis

The system potential energy includes the following three parts: the potential energy U_1 caused by the chain itself; the potential energy U_2 is the contact between link and rope locking force transmitting frame; third potential energy U_3 caused by the spring stiffness of the lock rope thrust frame. The first part of the potential energy U_1 is analyzed as follows.

In the transmission process, both ends of the drive chain are affected by the centrifugal tension except for the initial static tension T_0 . Therefore, the total dynamic tension at both ends of the transmission chain can be expressed as:

$$\hat{T} = T_0 + \hat{m}\nu^2,\tag{7}$$

where \hat{m} is mass per unit length of chain link; \hat{T} is tension on both ends of the chain.

b) New equilibrium state of the chain under transverse force
 Fig. 3. Diagrammatic sketch of chain stiffness analysis

As shown in Fig. 3(a), the chain link with the effect of tension will show the level position balance under the condition of the chain weight is relatively small and can be neglected. If the chain link *i* is applied on a vertical upward force P_i , as shown in Fig. 3(b), the hinge center of the

chain link *i* will produce a lateral displacement. A new equilibrium is obtained:

$$\begin{cases} \hat{T}\sin\alpha_i + \hat{T}\sin\alpha_{i-1} = P_i, \\ \hat{T}\cos\alpha_i + \hat{T}\cos\alpha_{i-1} = 0, \end{cases}$$
(8)

where α_i and α_{i-1} are the angle between the horizontal line and the connection chain link *i* hinge center.

As shown in Fig. 3(b) shows, this angle can be expressed as follows by displacement y_i :

$$\begin{cases} \sin \alpha_{i-1} = \frac{y_i - y_{i-1}}{h}, \\ \sin \alpha_i = \frac{y_{i+1} - y_i}{h}. \end{cases}$$
(9)

Putting Eq. (9) into Eq. (8) brings the following result:

$$\hat{T}\frac{y_i - y_{i-1}}{h} - \hat{T}\frac{y_{i+1} - y_i}{h} = P_i.$$
(10)

According to the Eq. (10), both i = 0 and i = N can be drawn as follows:

$$\begin{cases} \hat{T} \frac{y_0}{h} = P_0, \\ \hat{T} \frac{y_N}{h} = P_N. \end{cases}$$
(11)

According to the Eq. (10) and Eq. (11), the following conclusions can be drawn:

$$\begin{cases} \hat{T} \frac{y_0}{h} = P, \\ \hat{T} \frac{y_i - y_{i-1}}{h} - \hat{T} \frac{y_{i+1} - y_i}{h} = P_i, \\ \hat{T} \frac{y_0}{h} = P, \quad (i = 1, 2, ..., N - 1). \end{cases}$$
(12)

Eq. (12) is changed into matrix form:

$$Ky = P, (13)$$

where *P* is $\{P_1P_2 \cdots P_N\}$; *y* is $\{y_1y_2 \cdots y_N\}$; *K* is the chain link lateral static stiffness matrix. The chain link lateral static stiffness matrix *K* is as follows:

$$K = \begin{bmatrix} \frac{\hat{T}}{h} & -\frac{\hat{T}}{h} & & \\ -\frac{\hat{T}}{h} & \frac{2\hat{T}}{h} & -\frac{\hat{T}}{h} & & \\ & \ddots & \ddots & \ddots & \\ & & & -\frac{\hat{T}}{h} & \frac{2\hat{T}}{h} & -\frac{\hat{T}}{h} \\ & & & & -\frac{\hat{T}}{h} & \frac{\hat{T}}{h} \end{bmatrix}.$$
(14)

The potential energy U_1 caused by the chain itself can be expressed as:

$$U_1 = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} k_{ij} y_i y_j = \frac{1}{2} [y]^T [K] [y].$$
(15)

Putting Eq. (14) into Eq. (15) brings the following expression:

$$U_1 = \frac{\hat{T}}{2h} \sum_{i=1}^{N} (y_i - y_{i-1})^2.$$
(16)

Potential energy of the system is:

$$U = U_1 + U_2 + U_3 = \frac{\hat{T}}{2h} \cdot \frac{1}{2} \sum_{i=1}^{N} (y_i - y_{i-1})^2 + \frac{1}{2} k_c \sum_{i=n}^{n+m} \left(y_b - \frac{y_i + y_{i-1}}{2} \right)^2 + \frac{1}{2} k_b y_b^2,$$
(17)

where *n* shows serial number of the first chain link contacting thrust frame; *m* shows amount of all chain links contacting thrust frame; k_c is contact stiffness between chain link and force transmission frame; and k_b is spring stiffness in clamping the thrust frame.

3) System dissipation energy analysis

The system dissipation energy includes the following three parts: the dissipation energy S_1 caused by viscous damping between the chain links; the dissipation energy S_2 is the contact damping between link and rope locking force transmitting frame; third potential energy S_3 caused by the spring damping of the lock rope thrust frame.

The dissipation energy S_1 caused by viscous damping between the chain links can be expressed as:

$$S_{1} = \frac{1}{2}c_{i}\sum_{i=1}^{N} \left(\dot{\theta}_{i+1} - \dot{\theta}_{i}\right)^{2} = \frac{1}{2}c_{i}\sum_{i=1}^{N} \left(\frac{\dot{y}_{i+1} - \dot{y}_{i}}{h} - \frac{\dot{y}_{i} - \dot{y}_{i-1}}{h}\right)^{2}.$$
(18)

Dissipated energy of the system is:

$$S = S_{1} + S_{2} + S_{3} = \frac{1}{2}c_{i}\sum_{i=1}^{N} \left(\frac{\dot{y}_{i+1} - \dot{y}_{i}}{h} - \frac{\dot{y}_{i} - \dot{y}_{i-1}}{h}\right)^{2} + \frac{1}{2}c_{c}\sum_{i=n}^{n+m} \left(\dot{y}_{b} - \frac{\dot{y}_{i} + \dot{y}_{i-1}}{2}\right)^{2} + \frac{1}{2}c_{b}\dot{y}_{b}^{2},$$
(19)

where c_i is viscous damping between chain links; c_c is viscous damping between chain link and guide rail; and c_b is viscous damping between guide rail and tight spring.

Putting the three formulas above into Lagrange equation brings the following result:

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{q}_i}\right) - \frac{\partial T}{\partial q_i} + \frac{\partial U}{\partial q_i} + \frac{\partial S}{\partial \dot{q}_i} = Q_i,\tag{20}$$

where q_i is generalized coordinates; and Q_i is generalized force.

Transverse vibration dynamics equation of chain transmission system can be got by applying Lagrange equation as:

$$M\ddot{Y} + C\dot{Y} + KY = F, \tag{21}$$

where Y, M, C, K and F are listed in Appendix.

3.2. Simulation analysis

A rope changer with chain transmission has been designed according to the load case of one vertical shaft lifting steel-rope with its relevant parameter shown in Table 1. Transverse vibration rule of the rope changer has been found with MATLAB simulation analysis.

There are 11 horizontal chain links in total and chain links from the fifth to the eighth are clamped tightly and contacts with the steel-rope. In the model, all damping coefficients are set as 0.03 equally. According to preliminary design, disc spring stiffness is 10^7 N/m. Since the lifting steel-rope contacts the chain link tightly-clamped by thrust frame in rope changing, transverse vibration of the lifting steel-rope is just identical to that of the tightly-clamped chain link. To analyze transverse vibration of different chain links at each moment, data of the representative second and fifth chain links are loaded, and chain link vibration displacements with chain link linear velocity equal to 0.43 and 0.215 are shown in Fig. 4 and Fig. 5.

Table 1. Parameter table of rope changer with chain transmission

Parameter	Chain pitch <i>h</i> / mm	Mass of chain link <i>m</i> / kg	Moment inertia of chain link $I / \text{kg} \cdot \text{m}^2$	Amount of horizontal chain links	Mass of thrust frame m_b / kg	Tension T / kN	Velocity v / ms ⁻¹
Value	150.12	15.26	0.0286	11	76.3	50	0 - 0.43

Fig. 4. Transverse vibration results of different chain links (v = 0.43 m/s)

Fig. 5. Transverse vibration results of different chain links (v = 0.215 m/s)

The key of the device lies in stability of lifting steel-rope running. Vibration of the rope is identical to that of the fifth chain link. In Fig. 6 shows the vibration displacements of lifting steel-rope of this rope changer with different running velocities.

Fig. 7 show transverse l vibration results of the lifting steel-rope with different disc spring stiffness. To show the influence of the disc spring stiffness, spring stiffness k_1 - k_4 have been set as 10^6 N/m, 10^7 N/m, 5×10^7 N/m, 10^8 N/m.

Following conclusions can be drawn through simulation: (1) Fig. 4 and Fig. 5 show that in all

working conditions, compared with the second chain link with no clamping force from thrust frame, the fifth chain link tightly-clamped by thrust frame and contacting the lifting steel-rope has a smaller transverse vibration amplitude with a decrease of about 80 % in amplitude; and that proves that rope locking module plays a significant inhibitory effect on transverse vibration of steel-rope. (2) Decrease of rope changing velocity can slightly weaken transverse vibration of the steel-rope at low running velocity, yet the effect is quite small. (3) Disc spring stiffness coefficient has significant influence on transverse vibration amplitude of steel-rope, and transverse vibration amplitude decreases with increasing disc spring stiffness; however, after the stiffness reaches the value of K3 (5×10^7 N/m), the limitation becomes insignificant.

Fig. 6. Transverse vibration results of different running velocities

Fig. 7. Transverse vibration results with different disc spring stiffness (v = 0.43 m/s)

4. Experimental study

On the basis of above theoretical analysis and transverse vibration dynamic simulation, a rope changer prototype has been designed and made in accordance with actual parameters of lifting steel-rope in a mine with disc spring stiffness as 10^7 N/m. To verify the performance of the device and correctness of theoretical analysis and calculation, a simulating platform of lifting system has been built.

Fig. 8 shows schematic diagram of test platform of the rope changer with clamping chain transmission. Test support frame welded by profile steel simulates lifting shaft, lifting load container simulates rope weight load, and test instruments are placed on the test support platform and all assembly units are fixed to foundation supporting structure with bolts.

A testing sensor (X direction) for transverse vibration of steel-rope is fixed on the rope to transfer real-time dynamic transverse vibration displacement of the rope to data acquisition instrument and record data with a computer.

Fig. 9 shows test site arrangement plan. The steel-rope keeps running in the experiment so repeated vibration tests are conducted. The vibration test data 5 seconds under normal running are chosen from exporting data and make a comparation to vibration simulation data with 10-15 s, which is stable and representative with MATLAB tools.

Fig. 8. Schematic diagram of test platform of the rope changer with clamping chain transmission

Fig. 9. Test site map of steel-rope vibration experiment during rope changing

Comparisons of test and theoretical calculating values for steel-rope transverse vibration displacements with rope changing velocity as 0.43 m/s, 0.215 m/s and 0.11 m/s are shown respectively in Fig. 10 to Fig. 12.

The maximum transverse vibration amplitude is a key indicator of security and stability of the device in rope changing. Data from Fig. 10 to Fig. 12 have been processed to show the change of maximum amplitudes of steel-rope and unclamped chain links at different velocities in Fig. 13.

Fig. 10. Comparison of test and theoretical calculation of transverse vibration (v = 0.43 m/s)

These experimental data contribute to following conclusions: (1) From Fig. 10 to Fig. 12, the general trend of transverse vibration of the steel-rope and unclamped chain links in the experiment is obtained, which is basically consistent with theoretical calculation, though larger vibration

amplitude appearing partially at a certain moment due to other external reasons, which verifies the correctness of theoretical calculation. Moreover, maximum transverse amplitude is no greater than 0.4 mm in the whole experiment with different velocities of rope changing. (2) As is shown in Fig. 13, transverse vibration amplitude of the steel-rope slightly increases with increasing rope changing velocity, indicating rope changing velocity has comparatively less effect on transverse vibration of steel-rope at low velocities. (3) By comparison of the maximum amplitudes of unclamped chain links and steel-rope in Fig. 13, significant inhibitory effect of the locking module on transverse vibration of chain transmission can be shown, with amplitude decreasing rate at 80 %-90 %, and inhibitory effect becomes more obvious with the increase of rope changing velocity.

Fig. 11. Comparison of test and theoretical calculation of transverse vibration (v = 0.215 m/s)

Fig. 12. Comparison of test and theoretical calculation of transverse vibration (v = 0.11 m/s)

Fig. 13. Comparison of the maximum amplitudes at different velocities

In brief, experimental results show the rope changer with clamping chain transmission constrains transverse vibration of the steel-rope caused by polygon effect of chain transmission and makes the rope run with greater security, continuity and stability.

5. Conclusions

1) Despite the inevitable existence of polygon effect in rope changer with chain transmission, adding compaction mechanism can decrease transverse vibration caused by this excitation significantly with a decrease of about 80 % in vibration amplitude.

2) For system parameters of the rope changer, transverse vibration amplitude can be effectively restrained by increasing disc spring stiffness whose value reaching 5×10^7 N/m can make the inhibitory effect tends. However low rope changing velocity have little influence on transverse vibration amplitude of steel-rope.

3) The general trend of transverse vibration of the steel-rope and unclamped chain links in the experiment are basically consistent with theoretical calculation, which verifies the correctness of theoretical calculation.

4) The conclusion of the study can be used for the continuous transportation and recovery of pipeline structure parts, especially can be used for pipeline parts driving in the heavy load conditions.

Appendix

$$K = \begin{bmatrix} \theta_{1} & \omega_{1} & & & & \\ & \ddots & \theta_{n-1} & \omega_{n-1} & & & \\ & \omega_{n-1} & \theta_{n} + \frac{k_{c}}{4} & \omega_{n} + \frac{k_{c}}{4} & & & & \\ & \omega_{n-1} & + \frac{k_{c}}{4} & \theta_{n+1} + \frac{k_{c}}{2} & \omega_{n+1} + \frac{k_{c}}{4} & & & & \\ & \omega_{n+1} + \frac{k_{c}}{4} & \ddots & & & & \\ & & \ddots & \theta_{m-1} + \frac{k_{c}}{2} & \omega_{m-1} + \frac{k_{c}}{4} & \omega_{m} & & & -k_{c} \\ & & & \omega_{m-1} + \frac{k_{c}}{4} & \theta_{m} + \frac{k_{c}}{4} & \omega_{m} & & & -\frac{k_{c}}{2} \\ & & & \omega_{m-1} + \frac{k_{c}}{4} & \theta_{m} + \frac{k_{c}}{4} & \omega_{m} & & & -\frac{k_{c}}{2} \\ & & & \omega_{m-2} & \theta_{m-1} & & \\ & & & & \ddots & \ddots & \omega_{N-2} \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & &$$

$$C = \begin{bmatrix} \frac{6c}{h^2} \varphi_1 & \frac{c}{h^2} \\ \varphi_1 & \frac{6c}{h^2} & \ddots & \ddots \\ \varphi_1 & \frac{6c}{h^2} & \ddots & \ddots \\ \varphi_1 & \frac{6c}{h^2} & \ddots & \ddots \\ \varphi_{n-2} & \frac{6c}{h^2} \\ & \ddots & \varphi_{n-2} & \frac{6c}{h^2} \\ & \frac{c}{h^2} & \varphi_{n-1} & \frac{6c}{h^2} + \frac{c_c}{4} \\ & \frac{c}{h^2} & \varphi_{n-1} & \frac{6c}{h^2} + \frac{c_c}{2} \\ & \frac{c}{h^2} & \varphi_{n-1} & \frac{6c}{h^2} + \frac{c_c}{2} \\ & \frac{c}{h^2} & \varphi_{n-1} + \frac{c_c}{4} & \frac{6c}{h^2} \\ & \frac{c}{h^2} & \varphi_{n-2} + \frac{c_c}{4} & \frac{6c}{h^2} \\ & & \ddots & \varphi_{m-2} + \frac{c_c}{4} & \frac{6c}{h^2} + \frac{c_c}{2} \\ & & \frac{c}{h^2} & \varphi_{m-1} + \frac{c_c}{4} & \frac{6c}{h^2} \\ & & \ddots & \varphi_{m-2} + \frac{c_c}{4} & \frac{6c}{h^2} + \frac{c_c}{2} \\ & & \frac{c}{h^2} & \varphi_{m-1} + \frac{c_c}{4} & \frac{6c}{h^2} \\ & & \frac{c}{h^2} & \varphi_{m-1} + \frac{c_c}{4} & \frac{6c}{h^2} \\ & & \frac{c}{h^2} & \varphi_{m-1} \\ & & \frac{c}{h^2} & \varphi_{m-3} & \frac{6c}{h^2} \\ & & & \frac{c}{h^2} & \varphi_{n-3} \\ & & & \frac{c}{h^2} & \varphi_{n-3} & \frac{6c}{h^2} \\ & & & \frac{c}{h^2} & \varphi_{n-2} \\ & & & \frac{c}{h^2} & \varphi_{n-2} & \frac{6c}{h^2} \\ & & & \frac{c}{h^2} & \varphi_{n-2} & \frac{c}{h^2} \\ & & & \frac{c}{h^2} & \frac{c}{h^2} & \frac{c}{h^2} \\ & & & \frac{c}{h^2} & \frac{c}{h^2} \\ & & \frac{c}{h^2} & \frac{c}{h^2} &$$

Two main factors contributing to transverse vibration of transmission chain are external and internal excitation; influenced by working condition, external excitation is complicated but apt to be controlled by taking measures, while internal excitation is inevitable. The latter is mainly caused by polygon effects, and by reviewing relevant literature, the expression of transverse amplitude can by expressed as:

$$y_{i} = A\sin(\varpi t), \quad (i = 1, 2, ..., N - 1),$$

$$F = \begin{bmatrix} -\beta_{1} \ddot{y}_{1} + \varphi_{1} \dot{y}_{1} - \omega_{1} y_{1} \\ c \\ \dot{h}^{2} \dot{y}_{1} \\ 0 \\ \vdots \\ 0 \\ c \\ \dot{h}^{2} \dot{y}_{N-1} \\ -\beta_{N-1} \ddot{y}_{N-1} - \varphi_{N-1} \dot{y}_{N-1} - \omega_{N-1} y_{N-1} \end{bmatrix}.$$

Baofu Kou received Ph.D. degree in Taiyuan University of Technology, Taiyuan, China, in 2015. Now he works at Taiyuan University of Science and Technology. His current research interests include mechanical dynamics, mechanical and electrical integration, mechanical optimization design.

Qiuzu Liu received Ph.D. degree in Taiyuan University of Technology, Taiyuan, China, in 2014. Now he works at Taiyuan University of Technology. His current research interests include system simulation analysis, dust control.

Ning Li received M.A. degree in Dalian University of Technology, Liaoning, Dalian, China, in 2016. Now he works at Bery Heavy Industries, Ltd. His current research interests include heavy machine design, mechanical modeling and simulation.
